Abstract

Triplications of the superior cerebellar arteries are rare cases but when present are culminating factors to thromboembolism and arteriosclerosis leading to infarction of areas supplied. We present a rare case of arterial plexus, where there were not only triplicated branches of the superior cerebellar but these anastomosed forming a single branch that later bifurcated normally lateral to the cerebral peduncles. This kind of formation is attributed to embryological mal-fusions of primitive neural arteries towards the basilar trunk. Anastomosis can be clinically important in neurovascular surgery ligation therefore caution should be taken not to damage the forming branches.

Keywords: Triplication; Anastomosis; Superior cerebellar artery

Case Presentation

During a postmortem procedure carried out at the Kampala City Council Authority (KCCA) mortuary, the basal arterial complex showed a unique pattern of branching of the superior cerebellar arteries in a 30 year old male cadaver. The terminal end of the basilar artery branched into seven arteries. i.e. two posterior cerebral arteries, three right and two left superior cerebellar arteries (Figure 1). The arterial plexus was formed in such a way that the two branches (branches A and B) of the Superior Cerebellar (SCA) arose from the right side of the basilar artery. One artery (branch B) bifurcated 1.33mm from the main trunk and its upper branch anastomosed with the previous branch A forming a single branch C. (Figure 2). The formed branch C later bifurcated into two branches lateral to the cerebral peduncles (Figure 3). Branch C appeared engorged with a diameter of 2.24mm compared to its forming arteries (1.3mm and 1.86mm). There were no perforating branches from the arteries.

Discussion

Variations of the SCAs have been observed in their origin, patterns of branching with other anomalies being fenestrations, tortuosity. Triplication cases have been reported by various studies though rarely compared to duplications which are either unilateral or bilateral. Padmavathi reported 23.3% bilateral duplication and 2% triplications [1]; Wankhede reported 17.5% unilateral duplications and 2.5% bilateral duplications [2] while Harrigan reported 26% bilateral duplications and 2% triplications [3]. Literature reviewed shows that, there are more single and duplicated SCA than triplicated cases among the populations studied. Most triplicated SCA were unilateral with a single branch of the SCA on the contralateral side. In this case the unique right triplication co-existed with a duplicated left SCA forming a unique plexus. In cases where the SCA branches were either duplicated or triplicated, there were also variant origins [4]. Some arteries arose from the Posterior Cerebral Artery (PCA) varying from the case presented where all branches arose normally

from the basilar trunk.

The SCAs are in close proximity with the oculomotor nerve which separates it from the PCA, the trochlear and the trigeminal nerves [5,6]. The impingement on the oculomotor nerve depends on

the angle between the PCA and the SCAs. Triplication of the SCA is most likely to reduce this angle limiting space occupied by both nerve and arteries especially in anastomosed state. This could lead to ocular complications in cases where the oculomotor and trochlear nerves are compromised.

We report an anastomosed kind of triplication where two branches of the triplicate join to continue as a single artery and later dividing into two caudal and rostra branches lateral to the cerebral peduncles [7]. The union of these branches could be as a result of failed fusion of the primitive neural SCAs towards the basilar trunk to form a single primary branch [5]. The anastomosed kind of triplication can be viewed as advantageous and disadvantageous to the bearer. Anastomosis of arteries usually provides an alternative pathway for blood supply in case one artery is to be ligated for neurovascular surgery [8] or in case of blockage by plaques. The plexus kind of arterial anastomosis is a culminating factor to atherosclerosis, thrombosis that compromise blood flow leading to infarctions. Duplicated and triplicated branches usually contain perforating branches therefore caution should be taken during neurovascular surgery especially at the clivus and the cerebellopontine angle [9].

Conclusion

Although triplication of the SCA is a rare case, their presence is a culminating factor to thromboembolism, arteriosclerosis and atheromas. In situations where the triplicated branches anastomose with one another, care should be taken not to damage the alternative branches during neurovascular surgeries. Triplicated branches are more likely to cause compression of the oculomotor nerve than in duplicated or single branch cases.
