Description

Current data confirm excellent durability in Transcatheter Aortic Valve Replacement (TAVR) with low incidence of Structural Valve Deterioration (SVD) [1]. Bicuspid valves may pose a risk for SVD [2].

A patient with severe calcific aortic stenosis was assigned to TAVR. MSCT showed a biscuspid valve type I with leaflet calcification (Figure 1A). TAVR with a selfexpanding prosthesis was performed successfully (Figure 1B-C). 5 years following, the patient was transferred with pulmonary congestion. Transesophageal echocardiography confirmed SVD with leaflet thickening compromising the prosthesis right leaflet (Figure 1D). The heart-team decided for valve-in-valve procedure using a balloon-expandable prosthesis. Leading to successful SVD control (Figure 1E-F) the patient was able to leave after 8 days.

The case points to limitations of TAVR in bicuspid valves:

Convincing short-term results should not raise expansion of TAVR in bicuspid valves due to possibly limited long-term results.

Routine echocardiographic controls are warranted in patients with risk for early SVD including bicuspid anatomy.
