Background: Maxillary anterior teeth play a crucial role in aesthetics, phonetics, and mastication. For successful orthodontic treatment evaluating the morphology of the alveolar bone and incisive canal would help in avoiding root resorption, dehiscence, and fenestration. This study is aimed to research the configurational relationships among maxillary incisors, alveolar bone, and incisive canal through Cone Beam Computerized Tomography (CBCT).

Methods: CBCT images of 35 orthodontic patients were evaluated for length of the canal (L); angles between the palatal plane and the maxillary alveolar border (θ_1), the incisive canal (θ_2), and maxillary incisor (θ_3); distance from the right maxillary incisor to the incisive canal (D). All the measurements were performed on sagittal plane with the exception of (D) which was made on axial plane. Statistical analysis was performed on the above parameters using two sample test and Pearson's correlation analysis.

Results: There was no statistically significant difference between males and females for all the variables although there were large interindividual variation. There was a positive moderate correlation between θ_1 and θ_2 (0.480), θ_1 and θ_3 (0.487), θ_2 and θ_3 (0.345). The mean value for L and D were 10.38mm and 4.14mm respectively.

Conclusion: There exists a large interindividual variability for incisive canal, proximity of incisors with that of incisive canal which could not be precisely predicted by the conventional cephalograms. The results of the study could be helpful clinically in planning orthodontic treatment for significant intrusion and retraction of maxillary incisors.

Introduction

While not specifically in the Hippocratic Oath, *primum non nocere* is believed to be derived from it and means first, do no harm or above all else, do no harm. In other words, before you do anything to a patient, make sure that you are not making matters worse. What good does it do to straighten teeth if in doing so you cause the patient to lose them? [1]. With regard to maxillary incisor movement, Ackerman et al. presented the concept of "envelope of discrepancy" [2], which describes the limitations of the range of orthodontic movement of the maxillary incisor [3]. Contact with hard tissue structures, such as the labial, palatal, or incisive canal cortical plates, is a risk factor for apical root resorption in the maxillary incisor [4-6], and it is one of the iatrogenic complications of orthodontic treatment. The incisive canal is an anatomic structure that runs posterior and more close to the roots of the central incisors in the median plane of the palatine process of the maxilla, surrounded by thick cortical bone [5,6]. It connects the floor of the nasal cavity with the palate and opens into the oral cavity as incisive foramen. It runs parallel to the maxillary central incisors and transmits nasopalatine vessels and nerves, branches of the maxillary division of the trigeminal nerve,

and the maxillary artery [7]. Because of proximity of incisive canal to the maxillary incisors, the surgical invasion and its complications of the incisive canal during dental procedures in maxillary incisor region can cause nonosseointegration of dental implants or sensory dysfunction [8,9]. The precise location of incisive canal in reference to the maxillary incisors isn't well documented within the orthodontic literature due to the difficulties in detecting incisive canal morphology using conventional twodimensional radiographs.

The objective of this study was to evaluate the morphologic features and the relationship between roots of maxillary incisors and the incisive canal using Cone Beam Computed Tomography (CBCT).

Materials and Methods**Subjects**

The study was carried out on the patients visiting the out-patient section of the Department of Orthodontics and Dentofacial Orthopaedics, AJ Institute of dental sciences, Mangaluru. CBCT scans were taken for those who required CBCT for diagnosis and treatment planning. The inclusion criteria include patients having lateral cephalogram, normal anteroposterior skeletal relationship

Figure 1:

(ANB of 0°- 4°), normal overjet and overbite with Class I molar relationship. The exclusion criteria were history of orthodontic treatment, missing or supernumerary maxillary incisors, prosthesis in relation to maxillary incisors, history of trauma to maxillary incisors, and congenital anomalies like cleft lip and palate. Based on the inclusion and exclusion criteria, 35 subjects were selected.

Methods

The data was obtained using NewTom GIANO NNT Scanner with the patient in upright position and head positioned along the Frankfort horizontal plane, running parallel to the floor. All the scans were taken using the same machine by the same operator. The operating parameters were set at 3mA and 90kV, dose of 80- 100 μSv and the scan time of 9 seconds. All CBCT images were taken using a large dentoalveolar field of view. It was determined that the sagittal plane was perpendicular to the axial plane and parallel to the plane passing through anterior nasal spine and posterior nasal spine.

CBCT images of 35 orthodontic patients were evaluated for the following measurements

- Length of the canal (L).
- Angles between the palatal plane and the maxillary alveolar border (θ1) the incisive canal (θ2) the maxillary incisor (θ3).
- Distance from the right maxillary incisor to the incisive canal (D) (Figure 1).

Results

Mean values of the variables (descriptive statistics)

See Table 1.

Pearson’s correlation test:

- Correlation between theta 1 and theta 2 is highly statistically

Table 1:

	Mean	Std. Deviation
theta 1	136.388	7.86421
theta 2	108.105	10.81246
theta 3	114.666	10.43686
Length of incisive canal	10.3857	3.11015
distance of the right maxillary incisor to the incisive canal	4.1486	0.86581

Table 2:

	Correlation coefficient	'p' value
theta 1 vs theta 2	0.48	0.004
theta 1 vs theta 3	0.487	0.003
theta 2 vs theta 3	0.345	0.043

Figure 2: Scatter Plot for theta 1 vs theta 2.

significant (p=0.004). There is a positive moderate correlation between theta 1 and theta 2 (0.480).

- Correlation between theta 1 and theta 3 is highly statistically significant (p=0.003). There is a positive moderate correlation between theta 1 and theta 3 (0.487).
- Correlation between theta 2 and theta 3 is statistically significant (p=0.043). There is a positive moderate correlation between theta 2 and theta 3 (0.345) (Table 1 and Figure 2,3).

There is a positive moderate correlation between θ1 and θ2 (0.480), θ1 and θ3 (0.487), θ2 and θ3 (0.345).

The mean value for L and D are 10.38mm and 4.14mm respectively.

There are large interindividual variation although there were no significant differences between males and females.

Discussion

- This is the first study involving the Mangaluru population to investigate the anatomical characteristics of maxillary incisors, the incisive canal, and the maxillary alveolar border using CBCT images.

Figure 3: Scatter Plot for theta 2 vs theta 3.

- Inclination of maxillary incisors is significantly correlated with those of the maxillary alveolar border and axis of the incisive canal.

- First, in the present study, the length of the incisive canal in male patients is similar to that in female patients, which is discordant with the findings of a previous study [10].

- The FOV of CBCT images in the present study is larger in comparison with those reported in previous studies [12].

- The average anterior-posterior distance between the maxillary central incisor roots and the incisive canal measured is 4.14 which is lesser than previous studies [11]. This 4.14mm distance does not necessarily imply the “safety zone” for retraction because individuals with relatively large interroot distances are not at risk of canal invasion or contact even following maximum retraction. However, a large diversity in anatomy, morphology and size of the incisive canal and incisive foramen in different people are frequently reported with three-dimensional evaluation. The incisive canal, in many circumstances, is deviated toward the right central incisor [6,13-15].

- Because of the proximity of maxillary incisors to incisive canal, the possibility of sensory dysfunction in the anterior region and failure of osseointegration has been reported in cases of contact of the incisive canal through surgical interventions such as dental implant placement [16,17].

Conclusion

- This study has the proximity between incisive canal and maxillary central measured at 4.14 which is quite less indicating the closeness of incisor root to the canal which would aid us in carrying out the orthodontic procedures effectively.

- This study demonstrated that the incisive canal had large inter-individual variability, and the proximity between the incisive canal and the incisal root could not be precisely predicted by the conventional cephalogram.
