Abstract

The counterfeiting of printed documents is most common phenomenon in the modern world. The aim of the present research is to examine suspected documents from their ink components. 28 raw and processed toners were analyzed for their colored ink components by thin layer chromatography and high performance thin layer chromatography. Chloroform was efficient to extract all dye components from the inks. The separation was performed using two separate mobile phases. It is possible to differentiate toner cartridges by TLC and HPTLC.

Keywords: Questioned documents; Forensic analysis of ink; Toner; TLC; HPTLC

Introduction

The chemical examination of toners helps to determine whether similar or different inks are used to produce the whole document, to establish whether a document could have been produced on the purported date; or to determine the origin of a document [1]. The above questions can be answered by differentiating two toners formulations. Ink formula is a precise recipe or set of ingredients and their quantities that the manufacturer specifies for the final toners product. These ingredients are colorants (dyes and pigments) and vehicle components (volatile solvents, resins, etc.) [2].

The present study deals with the qualitative analysis of colored components of toners by thin layer chromatography (TLC) and high performance thin layer chromatography (HPTLC). TLC method is successfully used for the comparison of the toner but cannot be used as an identification method unless used for comparison with a complete collection of standards. HPTLC has been reported to be an automated form of TLC and has an inbuilt mechanism to store the database of analyzed toners samples which can be used for the comparison and identification.

Much of the work has been reported on the analysis of colored component of toner toners by thin layer chromatography [3-5] but limited work has been carried out to recognize the discrimination potential of high performance thin layer chromatography to analyze toners [6-8]. By keeping the above facts in minds, the present study is aimed to determine the discriminating potential of thin layer chromatography (TLC) and high performance thin layer chromatography (HPTLC) in order to differentiate the colored components of the toner toners samples.

Experimental

In the present study, an attempt has been made to classify the toners on the basis of the colorants (dyes and pigments) by using thin layer chromatography (TLC) and high performance thin layer

chromatography (HPTLC).

Collection of sample

Twenty eight raw as well as processed toner samples have been collected and were marked serially (Table 1). The raw toners were taken directly from the ink cartridge whereas a text was designed for the collection of processed toner sample. The text comprised of paragraphs in four colors, that is, cyan, magenta, yellow and black. The designed text was printed on A4 size sheets from different models of laser jet printers/photocopiers.

Sample preparation

The sample preparation of raw and processed toner samples were done separately and marked serially. In raw toner samples, 0.5 micrograms of each of four colors, that is, cyan, magenta, yellow and black were added into a test tube and mixed using 3 ml chloroform. In processed toner samples, total eight alphabets of four colors (two alphabets from each color) were selected from each printed document. Modified *Munson's technique* was used (Tandon *et al.* 1995) to remove toners from the processed toner samples. An aluminum foil was placed on the selected alphabets and the heat was applied on the back of sheet with a soldering rod (30 W) for 1-2 minutes. 2-3 lifts were sufficient to remove an adequate amount of sample. In another test tube, extracts of all four colors of each ink sample were mixed together using 2 ml chloroform. This was done because when a colored image (or printed stroke) was observed microscopically, all four colors visualized as series of dots. For example, if yellow color is

examined under the microscope, it is visualized as multiple dots of cyan, magenta, yellow and black color dots. However, they are not of equal intensity on substrate, but intensity of colors does not affect the results. Thus samples are considered as mixture of all colors. Also, the four colors, that is, cyan, magenta, yellow and black were used for printing the picture in layers. Hence, 4-colors were analyzed after mixing [9-10]. The similar process was done for the preparation of all the colored toners (raw and processed). The prepared mixture extracts were analyzed using thin layer chromatography (TLC) and high performance thin layer chromatography (HPTLC).

Solvent and stationery phase

The solvents used have been purchased from Loba Chemie Pvt. Ltd., Laboratory Reagent, Mumbai, India while the stationery phase from Merck, Germany. Ten different solvent systems (Table 2) were tried, of which two solvent systems (code I and II) were found to be efficient to separate all the toner samples. Both the solvent systems were kept in separate glass chambers for saturation for 35 minutes at

normal room temperature. The precoated silica gel G-60 F254 non fluorescent aluminum plates ($6.5 \times 20 \text{ cm}$) were used as the stationery phase.

Thin Layer Chromatography

The toner sample was spotted on precoated silica gel non-fluorescent aluminum plate 60 F254 (6.5 x 20 cm) with the help of fine capillary tube. Separate capillary tube was used for each sample. The spotted plate was kept for drying at normal room temperature for 15-20 minutes.

The dried spotted plate was placed gently in the saturated solvent chamber and was allowed to move vertically till it reached the 5 cm mark on the plate.

High Performance Thin Layer Chromatography

Instrumentation

HPTLC instrument consists of CAMAG (Muttenz, Switzerland) Linomat V sample applicator with 100 μl applicator syringe (Hamilton, Switzerland). Chromatography was performed on 6.5 cm \times 20 cm non fluorescent aluminum TLC plates precoated with silica gel 60- F254 (E. Merck, Darmstadt, Germany). CAMAG TLC scanner 4 was used for scanning the plates.

Sample application

The 3 µl of each prepared sample was applied on the plate in the

form of narrow bands of 6 mm length. The samples were applied under a continuous drying stream of nitrogen gas. The bands were applied 15 mm above from the bottom and 15 mm away from left edge of the plate.

Mobile phase and development

Plates were developed using two separate mobile phases consisting of ethyl acetate: ethanol: distilled water (70:35:30) and chloroform: methanol: n-hexane: acetic acid (85:25:5:1) respectively. Linear ascending development was carried out in a twin-trough glass chambers equilibrated with ten milliliters of the mobile phase. The mobile phase was allowed to migrate at a distance of 50 mm on plates. After development, the plates were dried completely. A similar process was carried out for all the toner samples.

Densitometric analysis

The densitometry scanning was performed with CAMAG TLC scanner 4 in the absorbance-reflectance mode under control by win CATS planar chromatography software (CAMAG, Switzerland). The source of radiation was the deuterium lamp, and bands were scanned at 540 nm. The samples showing absorbance at respective wavelength were recorded in the software in the form of 3D graphs (Figure 1).

Visualization of spots

The developed chromatograms were visualized under visible and ultraviolet light (short and long wavelength) and are shown in Figure

2. The developed visible and fluorescent spots/bands were recorded and their hR_c values were calculated as following:

hR_f (Distance travelled by solute / Distance travelled by solvent) x100

The results obtained were tabulated in Table 3 and 4.

Results and Discussion

Analysis by thin layer chromatography

Mixture of four colors, that is, cyan, magenta, yellow and black (CMYK) of twenty eight toner samples have been analyzed (Mizarchi et al.1998) using thin layer chromatography (TLC) and results obtained were observed in visible light and ultra violet light (short and long wavelength). The results have been interpreted on the basis of differences in the number, color and hR_f values of spots.

In solvent I, twenty one toner samples were differentiated from each other on the basis of the differences in the number, color and hR, value of the developed spots in the day light and ultra violet light (short and long wavelength). Remaining seven samples were put into three groups on the basis of similar number, color and hR value of the spots.

In solvent II, the sixteen samples were differentiated from each other on the basis of the differences in the number, color and hR, value of the developed spots in the day light and ultra violet light (short and long wavelength) . Remaining twelve samples were differentiated into six groups as they had similar number, color and hR, value of the spots and were put into.

Analysis by high performance thin layer chromatography

Two solvent systems [I and II] were used for the analysis of colored toners. In both solvent systems I and II all toner samples were differentiated from each other on the basis of the differences in the number, color and hR, value of the developed spots in the visible light at 540 nm (Table 5 and 6).

TLC has successfully differentiated toner samples on the basis of the differences in the number, color and hR, value of spots. However, some toner samples were not classified because they had similar chromatographic profiles. This might because of two reasons; first being the same type of dye might have been used by various manufacturers during ink formulation. Secondly, the toner ink might have been manufactured in bulk by one company and distributed under different brand names. For better differentiation and classification, the samples were analyzed by HPTLC and

encouraging results were obtained. More spots were detected when the chromatograms were scanned at 540 nm in absorption/reflectance mode in UV-VIS spectrophotometer. This was due to the high sensitivity of the densitometer which has detected even those spots which were not visible to the naked eyes. It was interesting to found that with increased number of spots different models of the

Table 6: Differentiation of toner samples by TLC and HPTLC with solvent system I and II

| Chromatographic Method | Solvent I | Solvent II |
|---------------------------|-----------|------------|
| TLC | 21 | 16 |
| HPTLC (540 nm) | 28 | 28 |

same make were also differentiated (Figure 3). In future studies bulk samples of different ink types could also be analyzed by HPTLC.

Conclusion

28 raw and processed toners were analyzed by thin layer chromatography (TLC) and high performance thin layer chromatography (HPTLC). Chloroform was used as an extraction solvent. Two solvent systems (code I and II) were used in combination to differentiate toner samples completely. The differentiation was done on the basis of the differences in the number, color and $hR_{\rm f}$ value of the developed spots. However, significant results have been obtained from the HPTLC chromatograms. It is possible to distinguish toner cartridges on the basis of the differences in the number, color and $hR_{\rm f}$ value of the spots.
