## Clinical Image

A 39-year-old male, presented with sudden onset of right upper quadrant. His past medical history is unremarkable. On physical examination, the patient looked ill and was not pale or jaundiced. He was hemodynamically stable and he had no signs suggestive of peritonitis. He had a normal renal, liver and coagulation screen.

An abdominal ultrasound revealed fluid collection around the right and left liver lobes suggestive of a hematoma. The CT scan of the abdomen showed 16 x 10 x 3 cm large hepatic sub capsular hematoma and no focal lesion (Figure 1). A diagnosis of hepatic sub capsular hematoma was made. The patient's symptoms resolved with conservative management. A follow up ultrasonography was done after 6 months and showed near complete resolution of the hematoma (Figure 2).

**Figure 1:** Abdominal computed tomography revealed 16 x 10 x 3 cm large hepatic sub capsular hematoma and no focal lesion.

**Figure 2:** Sonography showed near complete resolution of the hematoma.
