Abstract

Diabetes mellitus is being diagnosed in 0.3% of women at the reproductive stage of their life. Prevalence in Sri Lanka around 10% of the urban population. The prevention of congenital malformations in the newborns of pre-gestational diabetic mothers still constitutes one of the main problems in this group of patients in Sri Lanka.

Objectives: 1. To analyze the prevalence of fetal malformations in pre-gestational diabetic pregnancies compared to uncomplicated non diabetic pregnancies.

2. To evaluate the clinical utility of a comprehensive program inclusive of clinical features, glycemic assessment and prenatal detailed ultrasound with fetal echocardiography for congenital anomalies in pregnancies complicated by diabetes mellitus.

Methodology:

Study design: Hospital based prospective cohort study.

Study setting: De Soyza maternity hospital- Colombo, Sri Lanka.

Study period: August 2006 to August 2008.

Study population: 789 pre-gestational diabetic women who were registered in hospital clinics during Aug 2006 to Aug 2008 and their newborns. The results were compared with age and parity matched low risk non diabetic population of 780 antenatal mothers.

Study Instruments: Interviewer administered questionnaire included detailed history, examination checking glycemic assessment and comprehensive fetal ultrasonography inclusive of a standard four-chamber view of the heart and detailed power Doppler fetal echocardiography according to ISUOG standards. Glycemic control was set at 90-130mg/dl at pre and post prandial values and target HbA1C was set at below 6.2%.

Data collection: The purpose of the study was explained to the pregnant women and informed written consent was taken.

Data analysis: using the Statistical Package of Social Sciences (SPSS), version 17.0, did Data entry and analysis.

Results: Anomalies were identified in 49 of 789 (6%) fetuses and neonates: 12 central nervous system, 03 abdominal wall defects, 03 diaphragmatic hernias, 08 renal tract defects, 03 cystic hygromas, 02 isolated hydrothorax, 04 hydrops with multiple congenital abnormalities, 04 gastro intestinal malformations, 02 limb defects and 04 cardiac abnormalities were detected prenatally. 03 cardiac lesions 02 limb defect (VACTERAL) and down syndrome fetus detected postnatally. The results were compared with age and parity matched non diabetic control group of 780 routine visits mothers and antenatal admissions having 21/780 (2.7%) with only 1 cardiac abnormality this was significant $p < 0.08$ at (95% CI 0.77 – 5.03).

Central nervous system defects including hydrocephalus, holoporencephaly, encephalocele accounted for nearly 25% of total anomalies and renal tract abnormalities 15% all these anomalies in all systems except 3 cardiac and 2 limb defects were detected prenatally. Cardiac abnormalities including cardiac septum and great vessels, accounted for 15% of all fetal defects of which only 72% detected prenatally. Missed lesions were detected at neonatal 2D echo and these included a large ASD, a ventricular septal defect and PDA. There were seven neonatal deaths and five therapeutic pregnancy terminations associated with congenital anomalies. There were three fetal interventions done on 2 isolated renal obstructive uropathy and one hydrothorax with a success of 50%.

Recommendations and conclusion: This study demonstrates confirm the view that pre-gestational diabetic pregnancy, despite the improved metabolic control, is still a strong risk factor for alterations in fetal development leading to fetal malformations.

This study also demonstrate the advantage of a comprehensive program to detect fetal anomalies in pregnancies complicated by pre-gestational diabetes mellitus focusing further attention towards detecting fetal cardiac abnormalities.

Introduction

Diabetes mellitus is being diagnosed in 0.3% of women at the reproductive stage of their life. Prevalence in Srilanka around 10% of the urban population [1]. Metabolic disturbances related to glucose intolerance and hyperglycemia is known to affect the health and life of women planning motherhood. They can also impair the development of fetuses and newborns. Observations indicating a relationship between pre-gestational maternal diabetes and the occurrence of malformations were issued already by the end of the 19th century. Since then, numerous epidemiological studies have confirmed the assumption that a poorly controlled diabetes mellitus in pregnant women favors the development of fetal malformations [2].

The frequency of fetal developmental defects in diabetic pregnancies is 2–5 times higher compared to uncomplicated gestations. In the population of infants born to diabetic mothers, malformations are found in 2.7–16.8%, while in that born to healthy mothers they were only in 2–3% infants [3].

The early period of fetal development, i.e. the period of organogenesis (up to the 12th week of gestation), is of particular vulnerability in this respect. The influence of teratogenic factors during this period cause mostly large congenital defects, mainly of the central nervous system (CNS), the cardiovascular (CVS), skeletal, and urogenital systems [4].

The results of numerous studies show that the occurrence of congenital defects is much more frequent in infants born to mothers who presented with increased glycemia during the first trimester of pregnancy [5]. The etiology of malformations appearing in diabetic pregnancy is not entirely clear, but the results of many studies indicate particular metabolic states such as hyperglycemia, hypoglycemia, hyperketonemia, excessive formation of free oxygen radicals, undue production of insulin like growth factors, disturbed lipid and protein (lipoprotein) metabolism, deviation of the arachidonate metabolic pathway, divergent myoinositol metabolism, as well as a deficient supply of vitamins and microelements as the potential causal factors [6]. The unfavorable effect of diabetes mellitus on fetal development may also be derived from the impairment of blood vessel flow due to morphological changes in the capillary and arterial vessel walls. Among numerous effects of hyperglycemia, the teratogenic influence seems to be the best documented. The results of many studies indicate that a very strict control of maternal metabolism at the early stage of fetal development, preferably during the pre-conception period (in a planned pregnancy) results in a substantial decrease of the risk of malformation [7].

Defects occurring in the infants of diabetic mothers are of great variety, and it is impossible to distinguish malformations which would be specific for pregnancies complicated by diabetes mellitus. The caudal regression syndrome with femoral shortening seems to be the most characteristic malformation, because it is diagnosed 200–600 times more frequently in the population of newborns born to diabetic mothers (NDM) compared to newborns of non-diabetic mothers. In NDM, defects of the cardiovascular system, such as transposition of great vessels, septal defects, aortal coarctation, persisting arterial duct (PAD), single heart ventricle, ventricular hypotrophy, pulmonary stenosis, and situs inversus, constitute the most frequently observed malformations [8].

Malformations are also found in other parts of the body, such as the skeletal system (spinal defects and limb deformation) and the urogenital system (renal agenesis, polycystic renal degeneration, hydronephrosis, hypospady, and cryptorchism) [5].

Background

The prevention of congenital malformations in the newborns of pre-gestational diabetic mothers still constitutes one of the main problems in this group of patients in Srilanka.

Objectives

1. To analyze the prevalence of fetal malformations in pre-gestational diabetic pregnancies compared to uncomplicated non diabetic pregnancies [9].

2. To evaluate the clinical utility of a comprehensive program inclusive of clinical features, glycemic assessment and prenatal detailed ultrasound with fetal echocardiography for congenital anomalies in pregnancies complicated by diabetes mellitus [10].
Diagnosis of Fetal abnormalities “18 -23 weeks Fetal anomaly ultrasound scan and Doppler 12 (2)”9-55).

Methods

Study design: Hospital based prospective cohort study.

Study setting: De Soyza maternity hospital- Colombo, Sri Lanka.

Study period: August 2006 to August 2008.

Study population: 789 pre-gestational diabetic women who were registered in hospital clinics during Aug 2006 to Aug 2008 and their newborns. The results were compared with age and parity matched low risk non diabetic population of 780 antenatal mothers.

Study Instruments: Interviewer administered questionnaire included detailed history, examination checking glycemic assessment and comprehensive fetal ultrasonography inclusive of a standard four-chamber view of the heart and detailed power Doppler fetal echocardiography according to ISUOG standards. Glycemic control was set at 90-130mg/dl at pre and post prandial values and target HbA1C was set at below 6.2% [11].

Data collection: The purpose of the study was explained to the pregnant women and informed written consent was taken.

Data analysis: using the Statistical Package of Social Sciences (SPSS), version 17.0, did Data entry and analysis.

Results

Anomalies were identified in 49 of 789 (6%) fetuses and neonates: twelve central nervous system, three abdominal wall defects, three diaphragmatic hernias, eight renal tract defects, three cystic hygromas, two isolated hydrothorax, four hydrops with multiple congenital abnormalities, 04 gastro intestinal malformations, 02 limb defects and four cardiac abnormalities were detected prenatally. three cardiac lesions, two limb defect (VACTERAL) and down syndrome fetus detected postnatally. The results were compared with age and parity matched non diabetic control group of 780 routine visits mothers and antenatal admissions having 21/780 (2.7%) with only one cardiac abnormality this was significant $p < 0.08$ at (95% CI 0.77 – 5.03) [12].

Central nervous system defects including hydrocephalus, holoporencephaly, encephalocele accounted for nearly 25% of total anomalies and renal tract abnormalities 15% all these anomalies in all systems except 3 cardiac and 2 limb defects were detected prenatally. Cardiac abnormalities including cardiac septum and great vessels, accounted for 15% of all fetal defects of which only 72% detected prenatally. Missed lesions were detected at neonatal 2D echo and these included a large ASD, a ventricular septal defect and PDA. There were seven neonatal deaths and five therapeutic pregnancy terminations associated with congenital anomalies. There were three fetal interventions done on 2 isolated renal obstructive uropathy and one hydrothorax with a success of 50%.

Conclusion

This study demonstrates confirm the view that pre-gestational diabetic pregnancy, despite the improved metabolic control, is still a strong risk factor for alterations in fetal development leading to fetal malformations.

This study also demonstrate the advantage of a comprehensive program to detect fetal anomalies in pregnancies complicated by pre-gestational diabetes mellitus focusing further attention towards detecting fetal cardiac abnormalities.
